

Test Report — Use only individual cards

PR: kuantorflow#187 + kuantorflow_automation#42 · Issue: kuantorflow#127 · Date: 2026-08-02

Summary

A per-user view filter that hides everyone else's cards from the topic list, topic page, deck, quiz and the widget's chip refresh. Verified against a real database with two accounts side by side: the filtered account saw only its own two cards, while the other account saw all 53. **449 offline tests pass** (was 424). No schema change.

What changed

- ``individual_cards`` in `settings_store.DEFAULTS`, off by default — `BOOLEAN_KEYS` derives from `DEFAULTS`, so the setting itself is one line.
- ``utils._owner_clause()``, used by `get_topics(owner_id)` and `get_flashcards_by_topic(topic, owner_id)`. Filtering is in SQL so no page can render a card the query should not have returned.
- ``app.cards_owner_filter()`` — the only thing that decides whether a filter applies, returning `None` (no clause) when the setting is off *or* there is no account to filter by. Applied at all five read call sites.
- **Empty states** on the topic page, the topic list, the deck, and an extra line on the quiz — each says the filter is why, not "nothing here".
- **The checkbox** in the Settings popup, disabled for anonymous visitors, and a page reload after saving it (only this setting changes what the current page shows).

Automated tests

- **Added:** `tests/test_individual_cards.py` — 25 tests: the setting itself (default, type, junk fallback, round trip through `POST /settings`); which owner each of the five read paths asks for, and that an anonymous visitor is never filtered; the SQL actually built — **no clause** when unfiltered rather than `= NULL`, an equality clause bound as a parameter when filtered, and never an inequality; and the four empty states, including that they are unchanged when the filter is off.
- **Migrated:** every stub of `get_flashcards_by_topic / get_topics` for the new `owner_id` argument — 28 tests across 8 files were calling the old signature.
- **Suite result:** `pytest -m "not live"` — **449 passed, 6 skipped** (was 424 passed, 6 skipped).

Manual & browser verification

Against local MySQL, which already held 53 cards across six topics owned by the real account. A throwaway account was added with two cards of its own in a seventh topic, and both accounts were driven over real HTTP against the running server.

The filtered account:

Path	Filter off	Filter on
topic chips on /	7 topics	probe-own only
/topics.json	all	[["probe-own", 2]]
/flashcards/general	40 cards	0 + "No cards of your own..."
/flashcards/probe-own	2 cards	2 (probeword, probeword2)
/deck/general	cards	"No cards of your own in this topic..."
/deck/probe-own	2 cards	2, deck working (1 / 2, flip)
/quiz/general	quiz	"nothing to quiz on" + the filter note

The account next door, signed in throughout: still saw **all 7 topics including the probe account's**, and **all 40 cards** in general. The filter is per-user and lives in the query — it is not a global mode.

Turning it on was done through POST /settings, which returned the stored value, i.e. the same path the popup's Save uses.

Found during this run: the deck and the quiz still used their old "No flashcards saved under this topic yet" wording when the filter emptied them — the misleading message the topic page had already been fixed for. Both now name the filter, with tests.

Cleanup: probe cards, probe user row and settings/config-13.json removed; the database afterwards holds only the real account and its 53 cards.

Result

Pass. The filter shows only the user's own cards on every read path, leaves other accounts untouched, and explains itself wherever it empties a page.

Left deliberately:

- **Duplicate prevention stays global (#101)**, so a word saved by someone else is skipped even when hidden — the app can report "already in the database" about a card the user cannot see. Making dedup per-owner changes what is *stored* for everyone, so it is filed as #186 with options.
- **Not driven through a real Google sign-in** — the browser cannot be handed a session cookie (HttpOnly), so both accounts were driven over HTTP against the running server with minted sessions, and the rendered pages inspected.
