

Test Report — Reverso copy-paste .mht parser

PR: kuantorflow#<pending> · kuantorflow_automation#<pending> · Issue: kuantorflow#134 ·
Date: 2026-07-19

Summary

.mht notes that are OneNote copy-pastes of Reverso dictionary entries are now auto-detected and parsed into rich flashcards — one card per word + part of speech (senses aggregated), with explanation, usage examples, and translations. The glued (separator-less) translation terms are split back apart with Claude. Verified end-to-end against the real supplied file (docs/Voc Education June 12.mht), including a real save to the local DB; 8 new offline tests, suite 100 → **108 passed**.

What changed

- ``parsers.py`` — Reverso support:
- `_looks_like_reverso()` detects the format by its colour-coded markup (the POS `<span>` colour).
- `_reverso_entries()` walks the `<p>` blocks as a state machine (header → N. sense → explanation / usage example / example translation / glued translations, keyed by colour) into per-word entries with senses.
- `_reverso_cards()` builds **one card per word+POS**, aggregating senses: joined explanation, `examples_en` list, comma-joined translations, `examples_<lang>` list. Russian POS/Ukrainian POS → English POS via `REVERSO_POS_MAP`; Russian vs Ukrainian chosen by Cyrillic-specific letters.
- `_split_glued_translations()` sends the glued strings to Claude (haiku) and parses a JSON reply, keeping multi-word phrases together. **Graceful fallback**: no API key / offline / bad reply → the whole string is kept as one term, so parsing never breaks.
- `parse_mht_preview()` detects Reverso and dispatches to it; other notes fall back to the existing word — explanation line parser.
- ``app.py`` / ``templates/index.html`` — examples now survive the review popup: parsed `examples_en/ukr/rus` ride along as hidden JSON inputs (`tojson` | `forceescape`), and `add_card` decodes them into the saved card. (Auto-add mode already saved the full entry.)

Automated tests

- **Added:** `tests/test_reverso_parser.py` (6) — detection + full parse of a canned Reverso .mht (POS mapping, aggregated senses, split + de-duplicated translations, examples, readable source); one-card-per-POS; Ukrainian POS + language detection; non-Reverso .mht falling back to the line parser; and the split helper's reply-parsing + error-fallback (via an injected fake anthropic module, since the package isn't in the test venv). Plus

tests/test_lookup_and_cards.py (2) — add_card preserves example JSON and ignores malformed JSON.

- **Suite result:** `pytest -m "not live"` — **108 passed**, 1 skipped, 6 deselected (was 100).

Manual & end-to-end verification

Driven through the real upload route with the real file (the in-app browser has no file picker, so the multipart POST + local MySQL stand in for the UI):

- Uploaded docs/Voc Education June 12.mht → **3 cards** in the review popup: inquisitive/adjective, paramount/adjective, paramount/noun. → OK
- **Claude split every glued line correctly**, including the multi-word phrase: `верховный правитель``владыка` → `верховный правитель`, `владыка`. → OK
- Explanations aggregated with tidied parentheses; POS mapped (Прилагательное→adjective, Существительное→noun); language detected as Russian. → OK
- Saved all 3 to the local DB and re-read the flashcards page: **English examples and the Russian example sentences render**. → OK
- Test data cleaned up afterwards. Existing suite unaffected (100 → still green).

Result

Pass. Reverso copy-pastes parse into complete, correctly split cards, with examples preserved through save — matching the structure described in #134.
